Published by Pearson 2013

Version 8.0, August 2021
Book and slides

• The tables and graphs are the same as in the book
• See the book for references to original data sources
• Updated versions of the slides can be downloaded from the book web page www.globalfinancialsystems.org
“Plumbing”

- Refers to the infrastructure that makes the financial system work, and tools used by market participants
- We discuss a small subset, those most relevant to theme of book
- Derivatives
- Margins
- Payment systems
- CCPs
- Trading strategies including carry trades
- Securitization
• These slides combine content from
• Chapter 9: CCPs, trading strategies,
• And have some new content
• *Options, Futures, and Other Derivatives* by John Hull
Market participants

- General term referring to those who engage in trading
- Proprietary trading (*prop trading*) buying and selling for a financial institution’s own account, in order to make speculative profits
  - this is the target of the US Volcker rule, UK Independent Commission on Banking (Vickers report), EU Liikannen report
- Funds are financial institutions that invest on behalf of clients — e.g. Fidelity, BlackRock, Vanguard, etc. They are generally highly regulated (except hedge funds on next page)
- Family office is a specialized fund investing on behalf of a single investor (or family)
- Sovereign wealth fund is an institution investing on behalf of a country
Hedge funds (HFs)

Lightly but not unregulated

- Lightly regulated funds. Sometimes restricted to only sell to sophisticated and wealthy investors (*accredited*)
- Who consequentially should be able to take care of themselves (no need for micro-prudential protection)
- Still subject to securities laws and deal with regulated parts of the financial system
- Difficult to classify (except by absence of regulations)
- Before 2007 thought to be the main source of financial instability (echoes of 1998 and LTCM)
- We will see them in the endogenous risk chapter (and elsewhere)
Brokers and prime brokers

• Broker is a financial institution that facilitates transactions — sits in the middle of them

• Prime broker is a financial institution that provides financial services to hedge funds and other similar institutions
  1. credit
  2. trading
  3. risk management

• We will see them in the endogenous risk chapter and the case of Archegos below
Trading venues

- One can use OTC, but more formally
- The tradition is open outcry, still used on NYSE
- Today, electronic exchanges are the most common
Modern trading venues

• The distinction between trading on *exchanges* and trading *over the counter* (OTC) is of decreasing relevance ...

• Complex, bespoke, illiquid securities are only traded OTC through arrangements made *ad hoc*

• Many liquid securities can now be traded in several different venues, generally on *electronic trading networks* that *interoperate*

• *Dark pools* are trading venues that match buyers and sellers at prices established in other, ‘lit’ venues
  • Institutional traders try to reduce *price impact* of transacting big blocks of securities
Credit Markets
Where is the risk?

• Newspapers report equity markets (S&P 500, FT100, DAX, CAC40, NIKKEI, etc.)
• But the fixed income markets are much larger
Fixed income assets

- Provide payments on a fixed schedule
- Involving creditor(s) and debtor(s)
- Many categories, e.g.
  - plain vanilla bonds
  - loans
  - credit derivatives
- Usually traded in OTC markets
- Volume dwarves equity markets
- And are much more important
Credit risk

- Probability of default
- More generally chance of losing money
  - interest
  - rating
- Loss given default
Pari passu

- Debtors are considered in default as soon as they do not meet a payment obligation on any coupon or principal payment.
- "Pari passu" clauses mean that debtors are considered in default on all their debt obligations as soon as they default on any particular one.
- Note how this influences crises resolutions.
US fixed income markets

- Largest in the world
- Below we look at bonds and not bank loans
Real return on US markets

Global Financial Systems © 2021 Jon Danielsson, page 18 of 84
US treasury bond market

Intragovernmental:
- Government retirement funds: 80%
- Social security: 40%

Private:
- Mutual funds: 80%
- Foreign: 60%
- Fed: 40%
- Private: 100%
Foreign holders of US treasury debt

- Japan
- China
- United Kingdom
- Luxembourg
- Ireland
- United States
- Brazil
- Switzerland
- Belgium
- Hong Kong
- Singapore
- Taiwan
- Cayman Islands
- India
- Saudi Arabia
- France
- Other
Rating agencies

• Standard & Poors
• Moody’s
• Fitch
• + some new ones

Issue ratings on creditworthiness of borrowers

“A credit rating is S&P’s opinion of the general creditworthiness of an obligor, or the creditworthiness of an obligor with respect to a particular debt security or other financial obligation, based on relevant risk factors.”
## Ratings

*some grades missing from table*
Ratings process

- Financial analysis of balance sheet and P&L account
- Quality of management, expected growth of the industry
- Nature of this assessment is subjective
- Ratings usually reviewed once a year
Limitations of ratings

- Do not consider the impact of business cycles
- Assume transition probabilities constant over time
- Rating assumed to be *sole* determinant of default risk
- Not founded on a theory of the firm or on any theoretical stochastic processes for leveraged firms
- Not possible to use default correlations
Ratings and regulations

- Ratings are legally required for many purposes
- E.g. for a security to be repo-able with central banks
- Or as an input into bank capital calculations
- Many entities restricted to rated investments, often investment-grade
- Many take them seriously — others do not
- This makes ratings very sensitive politically
EU sovereign debt crisis

- Some EU countries have an AAA rating, others do not
- We discuss the sovereign debt crisis in detail later
They can make people angry

As Greece got further downgraded, European policies got undermined, provoking rage from EU politicians

“Europe can’t allow three private US enterprises to destroy the euro.” Either their “cartel” was smashed or “independent” European and Asian ratings agencies would be set up. “We can’t have a situation where a cartel of three US enterprises decides the fates of entire national economies and their citizens,” Viviane Reding, the then EU justice commissioner
Conflict of interest

- Ratings are generally solicited by the issuer of fixed income instruments
- Good ratings enhance marketability of the debt issue
- A rating agency is there to perform due diligence
- But it is paid a percentage based on the amount of financing
- If no debt issue, it will not get paid!

The rating agencies are amongst the most profitable financial firms
Case: Hannover Re and Moody’s

- CRAs made a big push into Europe in the early 1990s
- Allegedly used aggressive tactics to collect fees
- Moody’s informed the German insurance company Hannover Re in the mid 1990s that it had decided to rate the company at no charge, but was looking forward to the day Hannover Re was willing to pay for the ratings
- Hannover Re refused, and never paid Moody’s
- Moody’s rated Hannover Re anyway, starting with Aa2, in 1998, downgrading three times, eventually to Baa1 (near junk) in 2003
- S&P, which did get paid by Hannover Re, has rated it AA- from 2003 until 2012
- Moody’s stopped rating Hannover Re in 2008
Quality of ratings

- Rating agencies have always been criticized for the quality of their ratings.
- They have missed spectacular corporate failures.
- Also problems in individual countries:
  - Asia before the 1997 crisis.
  - European sovereigns before last year.
- Perhaps their worst failure relates to structured credit — discussed later.
So what can we do?

• Ratings are necessary
• And we don’t want them provided by the government, or under government control
• The current European attitude seems to be based on a desire to shoot the messenger
• More competition is beneficial — it is on the way
• It would be better if the issuers did not pay for rating
• It is tricky whether they should be held legally accountable
  • 1st amendment protection in US
• We do rely too much on them in regulation
Basic assets and derived assets

- Assets like equities (stocks), commodities and foreign exchange (FX) are known as **basic assets**
- A **derivative** is an asset whose properties derived from a basic asset, like forwards, futures, swaps and options
Forwards and futures

- A contract for delivery of asset at a predetermined price sometimes in the future
- I will buy $1.2 million from you for €1 million in one year

<table>
<thead>

</tbody>
</table>
Swaps

- The exchange of future payment flow from two assets
- I own a bond that pays €1 million in coupon payments every year for the next 10 years, you own a bond that pays $1.2 million every year for the next 10 years, and we agreed to swap the payment flow
Options

- A contract that gives the buyer the *right, but not the obligation* to enter into a transaction in the future
- It is a *contingent claim*
  - **Call** the buyer has the right to buy
  - **Put** The buyer has the right to sell foreign

**Option premium/price** The buyer pays a fee for the right, payable upfront
- Example next page
Example option

• An airline buys the right to purchase one barrel of oil one year from today at the price of $50
• If the price at the time exceeds $50 the airline enters into the transaction and otherwise not
• The price of such an option is obtained from the Black-Scholes equation
Margins

- Derivative transactions means that one of the counterparties may owe money to the other in the future.
- That means one counterparty faces credit risk.
- The financial institution that enters into a derivative transactions with a client will typically insist on some protection against that credit risk.
- Typically that is a *margin*.
Details

• A margin is a fraction of the contract amount that is kept in cash in a special account

Initial margin percentage of amount covered by cash or collateral in a margin account (e.g. 20%)

Maintenance margin amount that must be in the margin accounts (e.g. 50% of initial margin)
Example

• An airline enters into a contract with a bank for delivery of 1 million barrels of oil in one year at $50 million.
• Initial margin is 20% so the airline has to provide $10 million in cash upfront.
• If the price of oil falls to $40, the airline owes the bank $5 million, and will have to provide additional $5 million in margins to the margin account.
• That is a *margin call* and has typically to be met the same, or next day.
• Otherwise position is *liquidated*.
• Note how that can be destabilizing in a crisis.
Case: Archeos a $10 billion family office

- It had several prime brokers: Credit Suisse, Deutsche Bank, Goldman Sachs, Morgan Stanley, MUFG, Nomura, UBS and Wells Fargo
- All the prime brokers had an almost perfect view of its position
- Archeos traded swaps ($20 billion) which meant that when it’s positions went against it it had to provide margins to its prime broker
- And when it’s positions where in its favor, it could take money out of the margin account
• When Archeos was getting in serious difficulty, it ignored the margin calls
• Some prime brokers reacted immediately by liquidating its positions. They lost little or nothing
• That caused prices to fall, so those prime brokers who were slow lost significantly
• $20 billion fire stock sale
• Credit Suisse lost $5.5 billion
• Nomura $2.87 billion
Margins, haircuts and leverage

- Borrowed money and securities are used as leverage to increase the purchasing power of traders’ capital
Haircuts

• Similar to initial margin
• Securities pledged for collateral, only a portion of the current market value counts as pledge, the rest is haircut
• Term has other meanings, such as losses to bondholders in credit restructuring, like Greece
Mark–to–market

• Traditional accounting is historical values
• Misses changes in market values
• Hence marking–to–market
  • Relates to maintenance margin
Mark–to–model or magic

- What to do if there is no market?
- Exactly what happened in 2007
- Mark–to–model
- Those turned out to be unreliable
- So really marking–to–magic
Marking and financial stability

- Marking does provide useful protection
- But when used in a mechanistic fashion, it becomes *procyclical*
- People may stop trusting it in a crisis
- Giving rise to vicious endogenous risk feedback loops
- MTM is one of many approaches that fatten tails
Payment system
Payment system

- Used to settle payments by transferring money between economic agents
- Can refer to a narrow system, perhaps enabling one owner of a mobile phone to transfer money to another
- Or a national system, either directly operated by the government (typically central bank) or directly under its control
- Also refers to an international system like SWIFT
- The payment system is fundamentally to an efficient economy
- If it fails, economic activity grinds to a halt
- Nobody can make any electronic payments, including debit/credit cards
Examples

- Real-time gross settlement systems (RTGS). Immediate, no netting. Final and irrevocable
  - Eurosysten has TARGET2
  - Federal Reserve Banks, Fedwire (RTGS, for banks with accounts at the Fed)
- Private payment systems
- Visa, Mastercard, Apple Pay, Alipay, Paypal, Etherum, etc.
- Integrity of the payment systems is of primary national interest, including guarding against criminals, terrorists and hostile nation states
Central (clearing) counterparty (CCP)
Clearing and settlement

- There are a host of chores to do after trades are agreed ...
- *Clearing houses* mitigate counterparty risk among broker-dealers
- Depository Trust & Clearing Corp. in the U.S. cleared $1.48 quadrillion of trades and held $34 trillion of securities in trust in 2009
- Some clearing houses act as *central counterparties*, e.g. in many futures and options exchanges
CCPs

- One way to mitigate the systemic risk from CDSs, and the like is *central counterparties*
- But, will CCP create new systemic risk?
- Should eliminate asymmetric information
- Ideally one CCP or clear cross netting arrangements
- i.e. CCP is the legal counterparty to every market participant
- Promises to solve the problem of asymmetric information
- Many exchanges
  - Cross netting?
- They can not be allowed to go bust. See next slide
- National ambitions get in the way
But the CCP can not allowed to fail

- Huge amount of default risk concentrated in the CCP, and *everyone* is exposed to it
- Hong Kong CCP defaultes in 1980s
- Should the CB backstop it?
- Will it excessively increase margins during crisis and create *endogenous risk*?
- Ensuring the CCP is well capitalized means standardizing margining across the whole market: positive feedback
- Unless there’s just one CCP, clearing and netting between CCPs becomes an issue
Shadow banking

- Credit intermediation that involves entities and activities (fully or partly) outside the regular banking system
- Said differently, an operation that does banking without being called a bank
- Term created in 2007
- Before known as market-based finance or non-banks
- Now sometimes called *parallel banking* because shadow banking is seen as a negative term
- Historically mostly US
- But now widespread in most countries
Shadow banking

Collect deposits → Bank → Lend

Savers → Investments → Collective investment schemes → Securities → Borrowers

Peer-to-peer
Money market funds (MMF)

- The type of a shadow bank that raises most concerns is *money market mutual fund* — it can have many other names
- Intermediary that manages money
- Low-risk securities (commercial paper, certificates of deposits and treasuries)
- Ability to withdraw money at short notice
- Maintain the value of the principal of its assets
- Higher yield than bank accounts
- Big worry in US and especially China
Benefits of shadow banks

- If the banking system is inefficient
- Shadow banks can provide the cheaper alternative way of connecting savers with investors
- Has been a big benefit to the United States
- And establishing such a system is the objective of the European capital markets union — even if they wouldn’t use those words
Growth in non-bank assets

Assets of financial intermediaries

Total global financial assets

Share of total global financial assets

Exhibit 2-2
Why worry?

- Systemic risk
- Regulatory arbitrage
  - Asian crisis — Thailand
- Monetary policy transmission
- Channel for capital flows
- Unknown unknowns
Benefits — Shadow Parallel banking

- More competition
- More diverse financial system
- Financial inclusion
Trading strategies

- Rules used by traders when deciding what to buy and sell
- Can be highly formalized and automated (like HFTs)
- Or a vague preference for low–risk or safe investments
- Often are unconscious
- We have seen several examples, especially in the endogenous risk chapter
- Discuss momentum, value, technical trading, carry, short, HFT below
Value investing

- Find companies trading below their *inherent worth*
- Stocks with strong fundamentals like earnings, dividends, book value, cash flow
- The strategy of Warren Buffett
- One example of a mean reversion trade

 Seeking yield is maximizing risk

Warren Buffett
Technical trading

- Forecasting prices with quantitative methods
- Often successful with statistical arbitrage and HFT
- Less likely to work at lower frequencies
- Many studies proclaiming it works
- A problem with data mining. Forecasting in–sample not a proof of success
- Most public studies have methodological problems
- However, if someone is successful they will not really talk about it in any detail
Momentum — trend following

- Buying assets that have seen recent price increases and selling those that have fallen in price
- Can endogenously affect prices (self-validating in the short run)
- In the long run may cause bubbles and crashes
- May be conscious, but perhaps more likely done subconsciously
- For example, we only engage with successful managers
High–frequency trading (HFT)

• Using technology to beat everybody else
• Famous example Nathan Rothschild, pigeons and Napoleon’s defeat in Waterloo in 1815
• Now done with high–speed computers, data networks and algorithmic trading
• Main fears crystallized in the flash crash of May 2010
Shorts
Short selling

• Selling assets one does not own — borrow with the intention of buying back later
• In many cases a legitimate hedging activity
• But can be used to make directional speculative bets
• Difficulties in sorting out economic vs. political or moral arguments
Naked short selling

Two different activities

A. A short speculative position, rather than hedging
B. Short selling an asset without borrowing it
Shorts selling issues

- Profits from falling markets
- But is it any different from just selling assets one owns?
- Hard to see an economic distinction
- Hence the political/moral dimension of profiting from a crisis, or causing prices to fall
- Frequently banned
- However little empirical evidence indicating damage from short-selling or effectiveness of banning
Relevance to financial stability

- Most trading activities discussed here are not important for the stability of the entire financial system
- However, they can be one of the hidden mechanisms that culminates in a crisis
- Like a large, hidden, sell on loss strategy
- Flash crashes a big worry
Mechanics of a short

• A speculator borrows stock
• From somebody who intends to hold the stock but is happy to earn a fee for lending it
• The speculator commits to returning the stock at a predetermined date in the future
• The lender insists on a margin to protect themselves
• So the risk in shorting is either that the price increases or it temporarily increases and the speculator is unable to meet the margin
The Wirecard short

- Wirecard was a German financial institution that briefly became very large
- The Financial Times ran articles about how it might have been fraudulent
- Heavily shorted
- The German regulator, Bafin, prosecuted the FT and banned shorting
- Then Wirecard was revealed as having been fraudulent
- FT schadenfreude
- Head of Bafin was just fired
- Incredibly, Baffin staff was allowed to trade in Wireguard stock
Short squeeze

- Those shorting are vulnerable to short-term price movements
- Suppose someone quickly buys a lot of stock then the price increases
- And the speculator shorting is squeezed — short squeeze
- Because she will receive matching calls which have to be met on the same day
- If she can’t meet the margin call, her position is liquidated on the spot
Wolkswagen short squeeze 2008

- Porsche wanted more voting shares in WV, so started to buy its shares
- WV stock price increased, from €30 in 2005 to €150 in 2007 for no apparent reason, becoming the world’s most valuable automaker
- WV appeared massively overvalued (at height of a global crisis no cars selling) — speculators started shorting it
- Short position 12% of outstanding shares
- Porsche owned 43% and 32% in share options. The German government owned another 20.2%
- Not many shares to buy on the open market
- Speculators cover positions, price up to €1,000
- Losing $30 billion in the process to Porsche
- Highly controversial. Was it legal? Did the German regulators allow it to happen?
Gamestop (and some others)

- Gamestop had been seen by hedge funds as a company in difficulty
- That its stock price was destined to fall
- It was hence heavily shorted
- Then, small investors, coordinating via Reddid’s WallStreetBets page started to buy Gamestop on the Robinhood platform — squeezing the hedge funds
WallStreetBets (reddit) sentiment. Gamestop and SPY (SP-500 ETF)
Outcome

- The largest shorting hedge fund lost almost $3 billion — forced to close out position at the price high
- Robinhood was eventually forced to limit trading
- Robinhood clears trades via Depository Trust & Clearing Corp
- Lag between when investors orders and when cash is exchanged for securities, brokerages have to maintain deposit accounts at the clearinghouses
- DTCC wants $3 billion in collateral
- Robinhood eventually raised $2.4 billion from shareholders, allowing it to lift trading restrictions
Securitization

• The process of creating *asset-backed securities*
• Various types of credit type assets are *pooled* together (in a portfolio) and sold in various forms to creditors
• For example, credit card debt, car loans and mortgages
• Securitization with subprime mortgages was at the core of the crisis from 2007
Mechanics

• A firm has a pool of assets
  • e.g., corporate loans, mortgages credit card receivables
  • this company is known as the originator
• The originator creates a special purpose vehicle (SPV)
  • a separate legal firm under the control of the originator
• The SPV buys the assets from the originator and sells rights to the payment flow from the SPV
• The SPV is typically overcollateralized
  • value of assets exceeds the value of rights
• The difference is equity
Securitization chain

- Home owners
  - Borrow
  - Sell to Mortgage originators
- Investment bank
  - Credit Line
  - Premiums
  - Fees
  - Sells to Rating agencies
- Rating agencies
  - Fees
  - Sells to SPV
- SPV
  - Price
  - Premiums
  - Insurance companies
  - Interest & Principal
  - Sells to Investors
- Investors
“Bowie Bonds”

Bonds backed revenues of David Bowie’s 25 albums recorded before 1990. (Bowie was a 1960s and 1970s rock star). They were issued 1997, $55 million, paid an interest rate of 7.9% and had an average life of ten years.
Why securitise

- It allows banks to transfer risk
- Hence free up regulatory capital
- Credit becomes cheaper
- Investors can invest in previously inaccessible assets
- Credit risk resides with those who are most able to manage it
Drawbacks

- Lemon problem for buyer
- Moral hazard
  - e.g. originator only intends to hold on to a mortgage for a few months
  - so cares less about quality than if intending to hold to maturity
- Exposes originators to liquidity risk — like Northern Rock
